

Principles of Communications

Chapter 7: Optimal Receivers

Selected from Chapter 8.1-8.3, 8.4.6, 8.5.3 of
Fundamentals of Communications Systems, Pearson
Prentice Hall 2005, by Proakis & Salehi

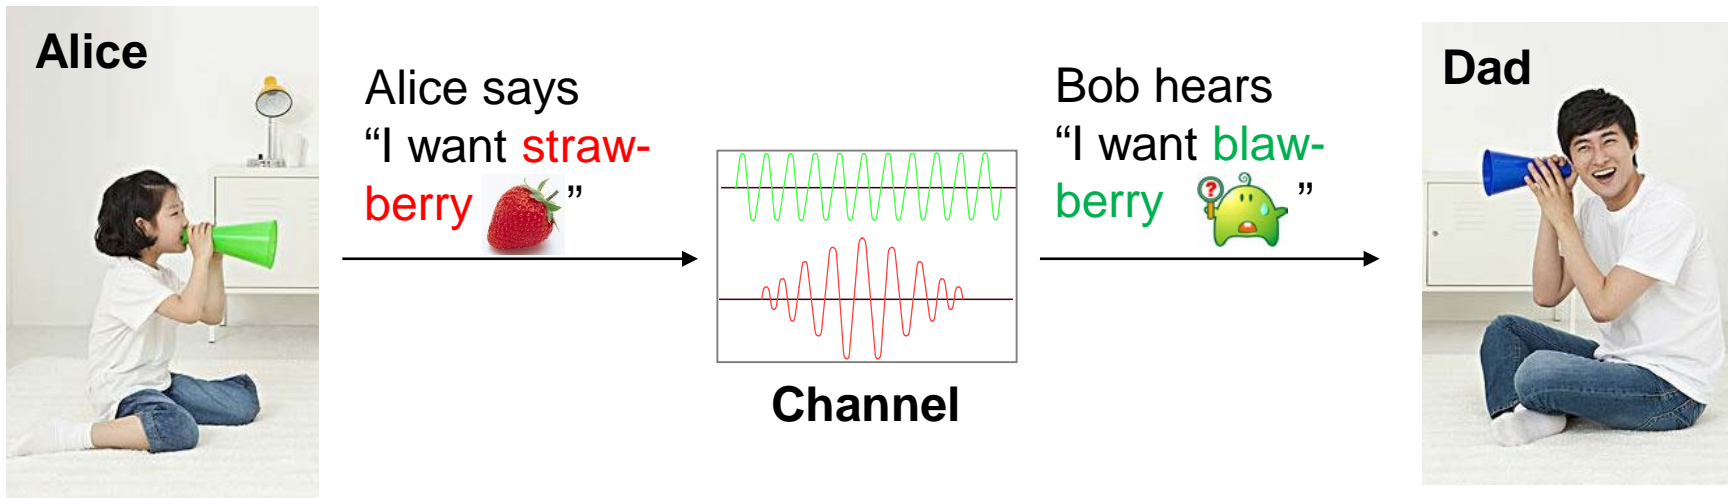

Topics to be Covered

- Detection theory
- Optimal receiver structure
- Matched filter
- Decision regions
- Error probability analysis

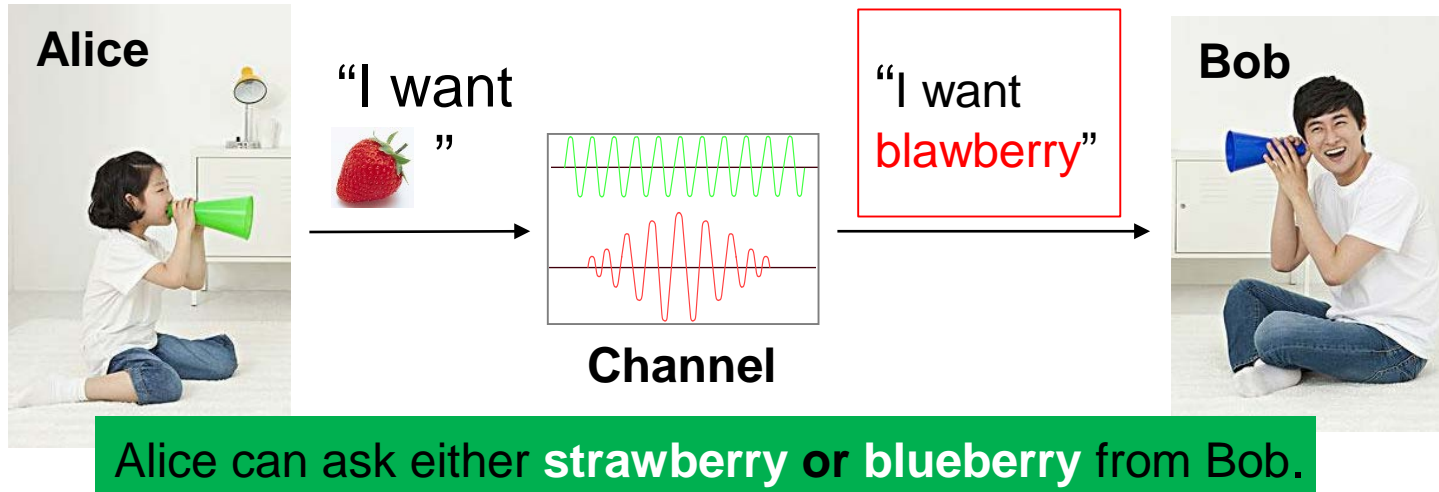

Example

- Alice tells her Dad that she wants either **strawberry**  or **blueberry** .

Why?

Statistical Decision Theory

- In digital communications, **hypotheses** are the possible messages and **observations** are the output of a channel
- Based on the observed values of the channel output, we are interested in the best decision making rule in the sense of minimizing the probability of error

Detection Theory

- Given M possible hypotheses H_i (signal m_i) with probability

$$P_i = P(m_i) \quad , \quad i = 1, 2, \dots, M$$

- P_i represents the **prior knowledge** concerning the probability of the signal m_i – **Prior Probability**
- The observation is some collection of N real values, denoted by $\vec{r} = (r_1, r_2, \dots, r_N)$ with conditional pdf
 $f(\vec{r}|m_i)$ -- conditional pdf of observation \vec{r} given the signal m_i
- Goal:** Find the best decision-making algorithm in the sense of minimizing the probability of decision error.

Observation Space

- In general, \vec{r} can be regarded as a point in some observation space
- Each hypothesis H_i is associated with a decision region D_i :
- The decision will be in favor of H_i if \vec{r} is in D_i
- Error occurs when a decision is made in favor of another when the signals \vec{r} falls outside the decision region D_i

MAP Decision Criterion

- Consider a decision rule based on the computation of the **posterior probabilities** defined as

$$P(m_i|\vec{r}) = P(\text{ signal } m_i \text{ was transmitted given } \vec{r} \text{ observed })$$

for $i = 1, \dots, M$

- Known as **a posterior** since the decision is made **after (or given) the observation**
- Different from the **a prior** where some information about the decision is known **in advance** of the observation

MAP Decision Criterion (cont'd)

- By Bayes' Rule:
$$P(m_i|\vec{r}) = \frac{P_i f(\vec{r}|m_i)}{f(\vec{r})}$$
- Since our criterion is to minimize the probability of detection error given \vec{r} , we deduce that the **optimum decision rule** is to choose $\hat{m} = m_k$ if and only if $P(m_i|\vec{r})$ is maximum for $i = k$.
- Equivalently,

Choose $\hat{m} = m_k$ if and only if
$$P_k f(\vec{r}|m_k) \geq P_i f(\vec{r}|m_i); \text{ for all } i \neq k$$

- This decision rule is known as **maximum a posterior** or **MAP** decision criterion

ML Decision Criterion

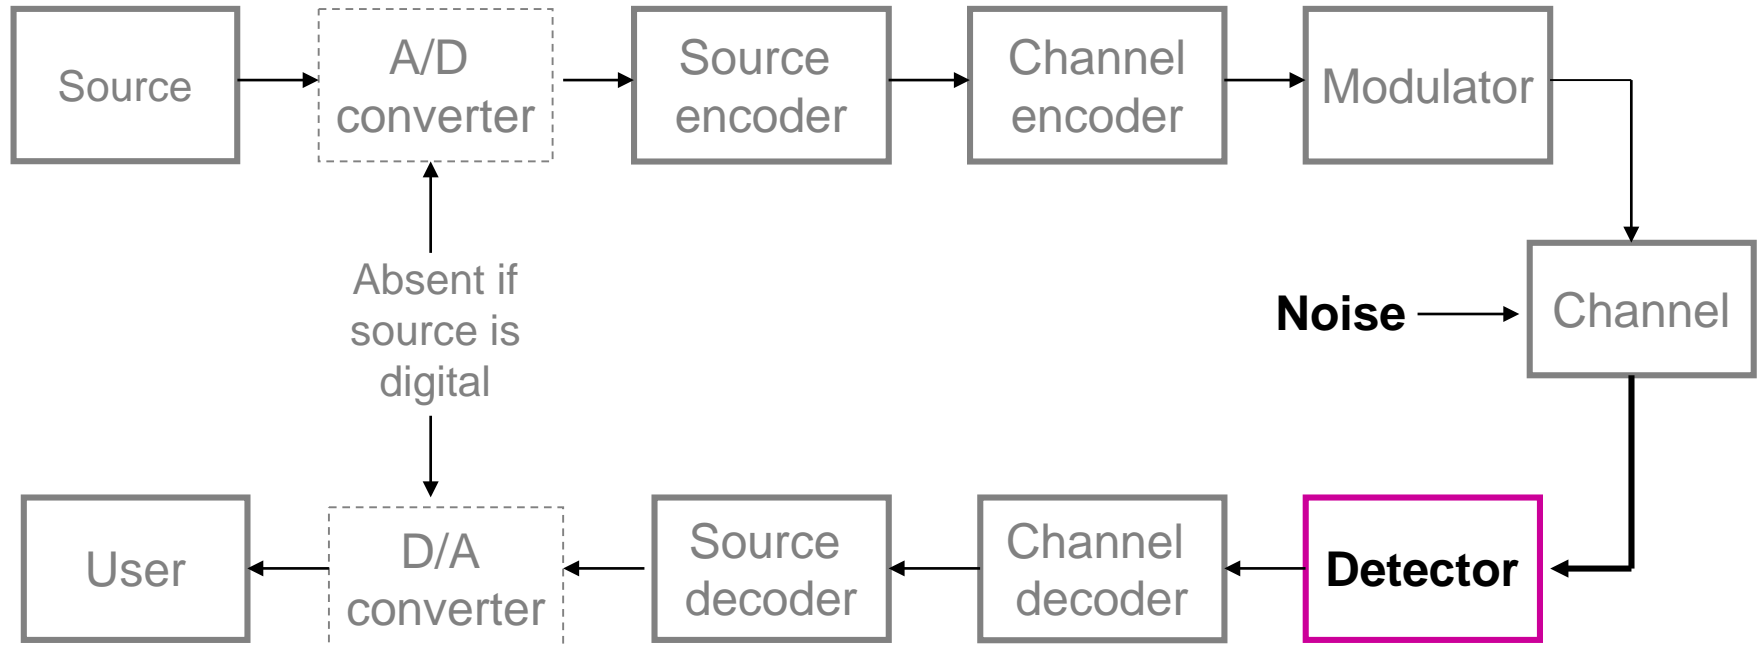

- If $p_1 = p_2 = \dots = p_M$, i.e. the signals $\{m_k\}$ are **equiprobable**, finding the signal that maximizes $P(m_k|\vec{r})$ is equivalent to finding the signal that maximizes $f(\vec{r}|m_k)$
- The conditional pdf $f(\vec{r}|m_k)$ is usually called the **likelihood function**. The decision criterion based on the maximum of $f(\vec{r}|m_k)$ is called the **Maximum-Likelihood (ML)** criterion.
- ML decision rule:

Choose $\hat{m} = m_k$ if and only if

$$f(\vec{r}|m_k) \geq f(\vec{r}|m_i); \text{ for all } i \neq k$$

- In any digital communication systems, the decision task ultimately reverts to one of these rules

Topics to be Covered

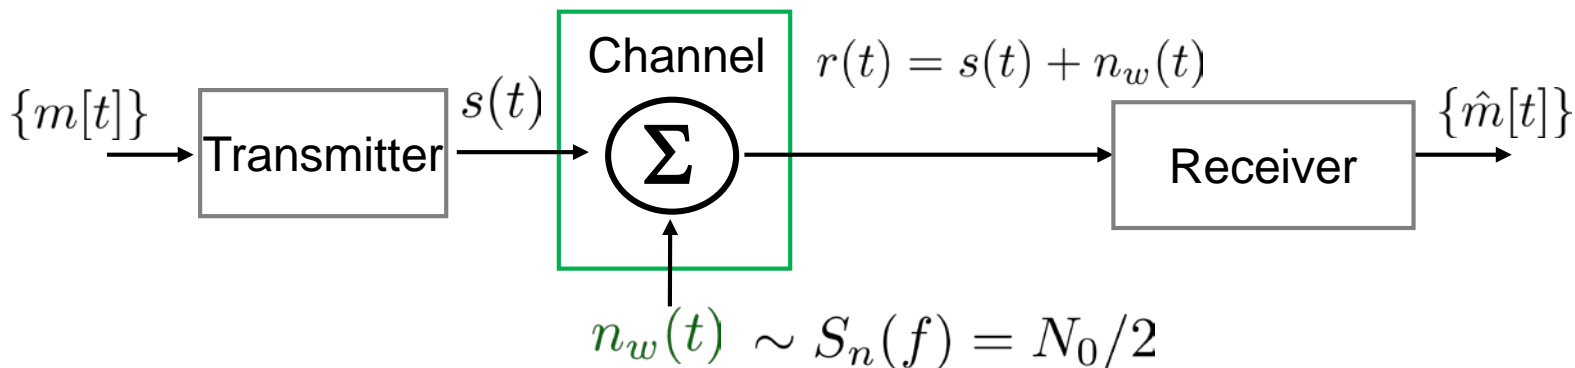

- Detection theory
- Optimal receiver structure
- Matched filter
- Decision regions
- Error probability analysis

Optimal Receiver in AWGN Channel

- Transmitter transmits a sequence of symbols or messages from a set of M symbols m_1, m_2, \dots, m_M with prior probabilities

$$p_1 = P(m_1), \quad p_2 = P(m_2), \quad p_M = P(m_M)$$

- The symbols are represented by finite energy waveforms $s_1(t), s_2(t), \dots, s_M(t)$, defined in the interval $[0, T]$
- The channel is assumed to corrupt the signal by **additive white Gaussian noise** (AWGN)

Signal Space Representation

- The signal space of $\{s_1(t), s_2(t), \dots, s_M(t)\}$ is assumed to be of dimension N ($N \leq M$)
- $\phi_k(t)$ for $k = 1, \dots, N$ will denote an orthonormal basis function
- Then each transmitted signal waveform can be represented as

$$s_m(t) = \sum_{k=1}^N s_{mk} \phi_k(t) \quad \text{where} \quad s_{mk} = \int_0^T s_m(t) \phi_k(t) dt$$

- Note that the noise $n_w(t)$ can be written as

$$n_w(t) = \underbrace{n_0(t)}_{\text{orthogonal to the space}} + \underbrace{\sum_{k=1}^N n_k \phi_k(t)}_{\text{Projection of } n_w(t) \text{ on the N-dim space}}$$

orthogonal to the space, falls outside the signal space spanned by $\{\phi_k(t), k = 1, \dots, N\}$

- The received signal can thus be represented as

$$r(t) = s(t) + n_w(t)$$

$$= \sum_{k=1}^N s_{mk} \phi_k(t) + \sum_{k=1}^N n_k \phi_k(t) + n_0(t)$$

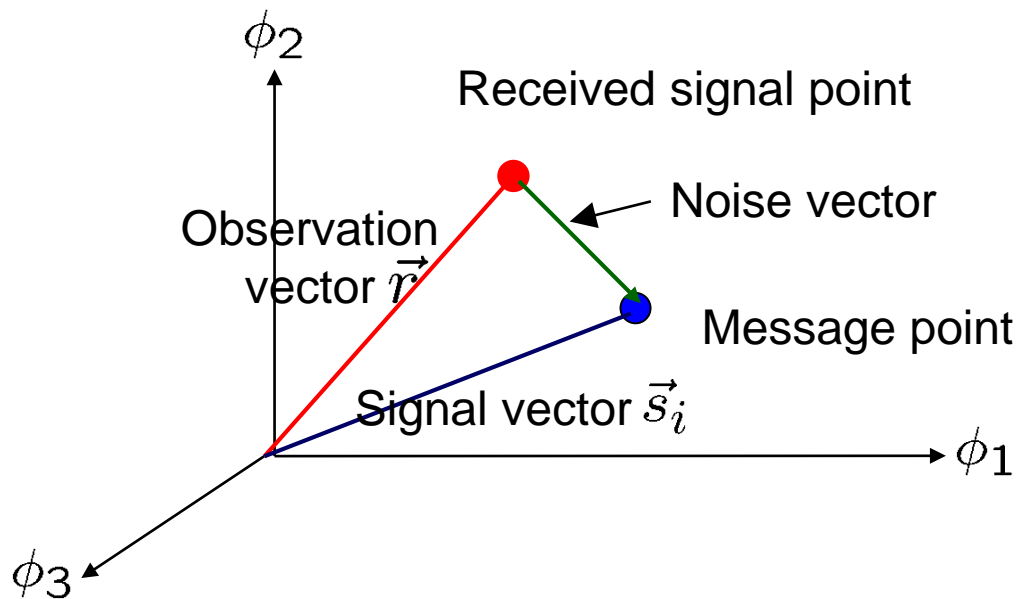

$$= \underbrace{\sum_{k=1}^N r_k \phi_k(t)}_{\text{Projection of } r(t) \text{ on N-dim signal space}} + n_0(t) \quad \text{where } r_k = s_{mk} + n_k$$

Projection of $r(t)$ on N-dim signal space

Graphical Illustration

- In vector forms, we have

$$\vec{r} = \vec{s}_i + \vec{n}$$

Receiver Structure

- Subdivide the receiver into two parts
 - **Signal demodulator**: to convert the received waveform $r(t)$ into an N-dim vector $\vec{r} = (r_1, r_2, \dots, r_N)$
 - **Detector**: to decide which of the M possible signal waveforms was transmitted based on observation of the vector \vec{r}

- Two realizations of the signal demodulator
 - Correlation-Type demodulator
 - Matched-Filter-Type demodulator

Topics to be Covered

- Detection theory
- Optimal receiver structure
- Matched filter
- Decision regions
- Error probability analysis

What is Matched Filter (匹配滤波器)?

- The matched filter (MF) is the optimal linear filter for **maximizing the output SNR**.
- Derivation of the MF

- Input signal component $s_i(t) \leftrightarrow A(f) = \int_{-\infty}^{\infty} s_i(t) e^{-j\omega t} dt$
- Input noise component $n_i(t)$ with PSD $S_{n_i}(f) = N_0 / 2$
- Output signal component $s_o(t) = \int_{-\infty}^{\infty} s_i(t - \tau) h(\tau) d\tau$
- Sample at $t = t_0$ $= \int_{-\infty}^{\infty} A(f) H(f) e^{j\omega t} df$

Output SNR

- At the sampling instance $t = t_0$, $s_o(t_0) = \int_{-\infty}^{\infty} A(f)H(f)e^{j\omega t_0} df$
- Average power of the output noise is

$$N = E\{n_o^2(t)\} = \frac{N_0}{2} \int_{-\infty}^{\infty} |H(f)|^2 df$$

- **Output SNR**

$$d = \frac{s_o^2(t_0)}{E\{n_o^2(t)\}} = \frac{\left[\int_{-\infty}^{\infty} A(f)H(f)e^{j\omega t_0} df \right]^2}{\frac{N_0}{2} \int_{-\infty}^{\infty} |H(f)|^2 df}$$

Find $H(f)$ that can maximize d

Maximum Output SNR

- Schwarz's inequality:

$$\int_{-\infty}^{\infty} |F(x)|^2 dx \int_{-\infty}^{\infty} |Q(x)|^2 dx \geq \left| \int_{-\infty}^{\infty} F^*(x) Q(x) dx \right|^2$$

equality holds when $F(x) = CQ(x)$

- Let $\begin{cases} F^*(x) = A(f) e^{j\omega t_0} \\ Q(f) = H(f) \end{cases}$, then

E : signal energy

$$d \leq \frac{\int_{-\infty}^{\infty} |A(f)|^2 df \int_{-\infty}^{\infty} |H(f)|^2 df}{\frac{N_0}{2} \int_{-\infty}^{\infty} |H(f)|^2 df} = \frac{\int_{-\infty}^{\infty} |A(f)|^2 df}{\frac{N_0}{2}} = \frac{2E}{N_0}$$

Solution of Matched Filter

- When the max output SNR $2E/N_0$ is achieved, we have

$$H_m(f) = A^*(f)e^{-j\omega t_0}$$
$$\updownarrow$$
$$h_m(t) = s_i^*(t_0 - t)$$

$$h_m(t) = \int_{-\infty}^{\infty} H_m(f)e^{j\omega t} df$$
$$= \int_{-\infty}^{\infty} A^*(f)e^{-j\omega(t_0-t)} df$$
$$= s_i^*(t_0 - t)$$

- Transfer function: **complex conjugate** of the input signal spectrum
- Impulse response: **time-reversal and delayed version** of the input signal $s(t)$

Properties of MF (1)

- Choice of t_0 versus the causality (因果性)

Properties of MF (2)

- Equivalent form – Correlator

- Let $s_i(t)$ be within $[0, T]$

$$y(t) = x(t) * h_m(t) = x(t) * s_i(T-t)$$

$$= \int_0^T x(\tau) s_i(T-t+\tau) d\tau$$

- Observe at sampling time $t = T$

$$y(T) = \int_0^T x(\tau) s_i(\tau) d\tau = \int_0^T x(t) s_i(t) dt$$

**Correlation
integration**
 (相关积分)

Correlation Integration

- Correlation function

$$R_{12}(\tau) = \int_{-\infty}^{\infty} s_1(t) s_2(t + \tau) dt = \int_{-\infty}^{\infty} s_1(t - \tau) s_2(t) dt = R_{21}(-\tau)$$

- Autocorrelation function $R(\tau) = \int_{-\infty}^{\infty} s(t) s(t + \tau) dt$

- $R(\tau) = R(-\tau)$

- $R(0) \geq R(\tau)$

- $R(0) = \int_{-\infty}^{\infty} s^2(t) dt = E$

- $R(\tau) \leftrightarrow |A(f)|^2 \quad R(0) = \int_{-\infty}^{\infty} s^2(t) dt = \int_{-\infty}^{\infty} |A(f)|^2 df$

Properties of MF (3)

- MF output is the autocorrelation function of input signal

$$\begin{aligned} s_o(t) &= \int_{-\infty}^{\infty} s_i(t-u) h_m(u) du = \int_{-\infty}^{\infty} s_i(t-u) s_i(t_0-u) du \\ &= \int_{-\infty}^{\infty} s_i(\mu) s_i[\mu+t-t_0] d\mu = R_{s_o}(t-t_0) \end{aligned}$$

- The peak value of $s_o(t)$ happens $t = t_0$

$$s_o(t_0) = \int_{-\infty}^{\infty} s_i^2(\mu) du = E$$

- $s_o(t)$ is symmetric at $t = t_0$

$$A_o(f) = A(f) H_m(f) = |A(f)|^2 e^{-j\omega t_0}$$

Properties of MF (4)

- MF output noise

- The statistical autocorrelation of $n_o(t)$ depends on the autocorrelation of $s_i(t)$

$$\begin{aligned} R_{n_o}(\tau) &= E\{n_o(t)n_o(t+\tau)\} = \frac{N_0}{2} \int_{-\infty}^{\infty} h_m(u)h_m(u+\tau)du \\ &= \frac{N_0}{2} \int_{-\infty}^{\infty} s_i(t)s_i(t-\tau)dt \end{aligned}$$

- Average power

$$\begin{aligned} E\{n_o^2(t)\} &= R_{n_o}(0) = \frac{N_0}{2} \int_{-\infty}^{\infty} s_i^2(\mu)du \quad \text{Time domain} \\ &= \frac{N_0}{2} \int_{-\infty}^{\infty} |A(f)|^2 df = \frac{N_0}{2} \int_{-\infty}^{\infty} |H_m(f)|^2 df \quad \text{Frequency domain} \\ &= \frac{N_0}{2} E \end{aligned}$$

Example: MF for a rectangular pulse

- Consider a rectangular pulse $s(t)$

$$E_s = A^2 T$$

- The impulse response of a filter matched to $s(t)$ is also a rectangular pulse
- The output of the matched filter $s_0(t)$ is $h(t) * s(t)$

- The output SNR is

$$(SNR)_o = \frac{2}{N_0} \int_0^T s^2(t) dt = \frac{2A^2 T}{N_0}$$

What if the noise is Colored?

- Basic idea: preprocess the combined signal and noise such that the non-white noise becomes white noise - **Whitening Process**

$x(t) = s_i(t) + n(t)$ where $n(t)$ is colored noise with PSD $S_n(f)$

Choose $H_1(f)$ so that $n'(t)$ is white, i.e.

$$S'_n(f) = |H_1(f)|^2 S_n(f) = C$$

$H_1(f), H_2(f)$

- $H_1(f) : |H_1(f)|^2 = \frac{C}{S_n(f)}$
- $H_2(f)$ should match with $S'(t)$ $A'(f) = H_1(f)A(f)$
 $H_2(f) = A'^*(f)e^{-j2\pi ft_0} = H_1^*(f)A^*(f)e^{-j2\pi ft_0}$
- Overall transfer function of the cascaded system:

$$\begin{aligned} H(f) &= H_1(f) \cdot H_2(f) = H_1(f)H_1^*(f)A^*(f)e^{-j2\pi ft_0} \\ &= |H_1(f)|^2 A^*(f)e^{-j2\pi ft_0} \end{aligned}$$

$$H(f) = \frac{A^*(f)}{S_n(f)} e^{-j2\pi ft_0}$$

MF for colored noise

Update

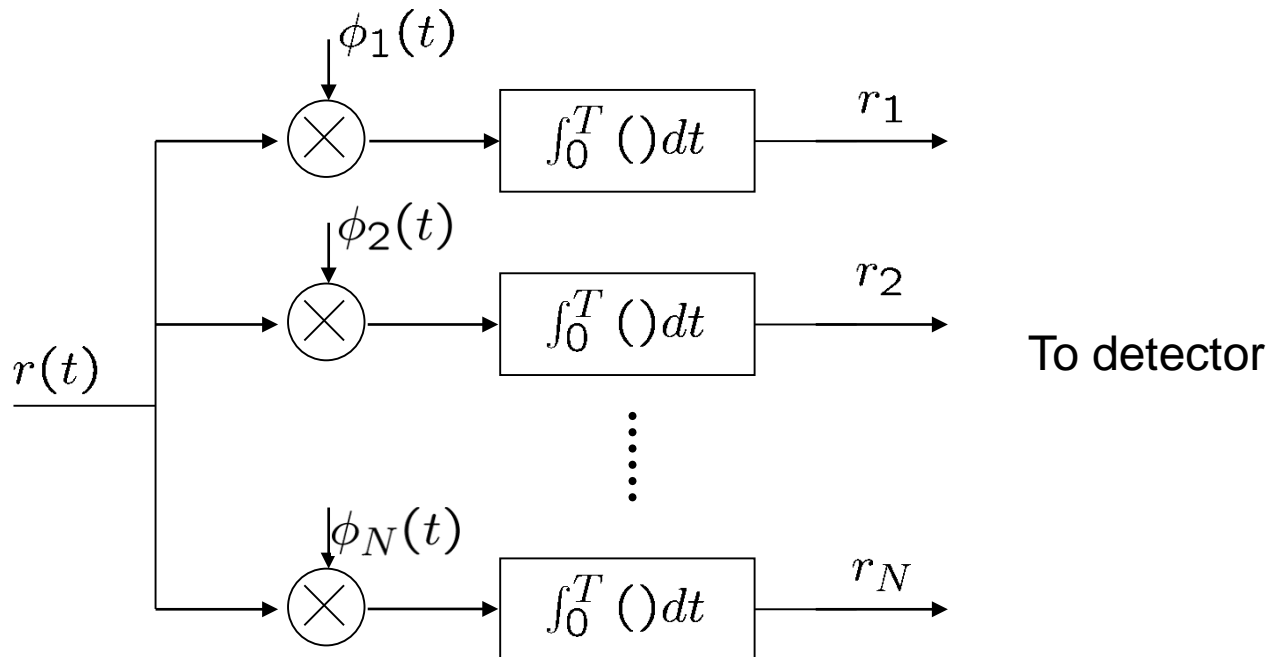

- We have discussed what is matched filter
- Let us now come back to the optimal receiver structure

- Two realizations of the signal demodulator
 - Correlation-Type demodulator
 - Matched-Filter-Type demodulator

Correlation Type Demodulator

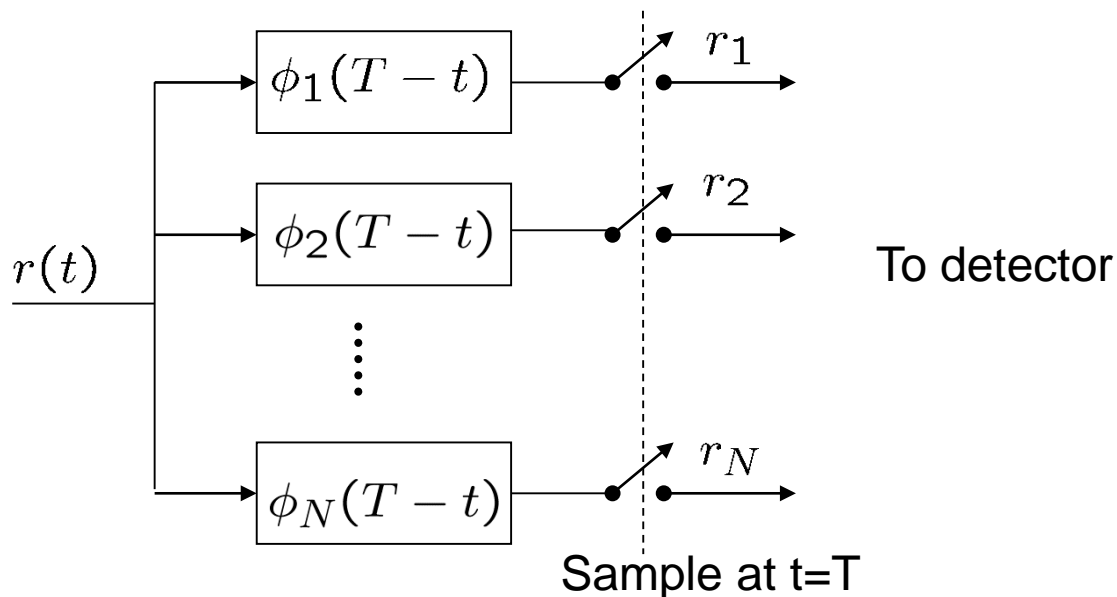

- The received signal $r(t)$ is passed through a parallel bank of N cross correlators which basically compute the projection of $r(t)$ onto the N basis functions $\{\phi_k(t), k = 1, \dots, N\}$

Matched-Filter Type Demodulator

- Alternatively, we may apply the received signal $r(t)$ to a bank of N matched filters and sample the output of filters at $t = T$. The impulse responses of the filters are

$$h_k(t) = \phi_k(T - t), \quad 0 \leq t \leq T$$

- We have demonstrated that
 - for a signal transmitted over an AWGN channel, either a correlation type demodulator or a matched filter type demodulator produces the vector $\vec{r} = (r_1, r_2, \dots, r_N)$ which contains all the necessary information in $r(t)$

- Now, we will discuss
 - the design of a signal detector that makes a decision of the transmitted signal in each signal interval based on the observation of \vec{r} , such that the probability of making an error is minimized (or correct probability is maximized)

Decision Rules

Recall that

- MAP decision rule:

choose $\hat{m} = m_k$ if and only if

$$P_k f(\vec{r}|m_k) > P_i f(\vec{r}|m_i); \text{ for all } i \neq k$$

- ML decision rule

choose $\hat{m} = m_k$ if and only if

$$f(\vec{r}|m_k) > f(\vec{r}|m_i); \text{ for all } i \neq k$$

In order to apply the MAP or ML rules, we need to evaluate the **likelihood function** $f(\vec{r}|m_k)$

Distribution of the Noise Vector

- Since $n_w(t)$ is a Gaussian random process,
 - $n_k = \int_0^T n_w(t)\phi_k(t)dt$ is a Gaussian random variable (from definition)
- Mean: $E[n_k] = \int_0^T E[n_w(t)]\phi_k(t)dt = 0$, $k = 1, \dots, N$
- Correlation between n_j and n_k

$$\begin{aligned}
 E[n_j n_k] &= E \left[\int_0^T n_w(t)\phi_j(t)dt \cdot \int_0^T n_w(\tau)\phi_k(\tau)d\tau \right] \\
 &= E \left[\int_0^T \int_0^T n_w(t)n_w(\tau)\phi_j(t)\phi_k(\tau)dtd\tau \right]
 \end{aligned}$$

PSD of $n_w(t)$ is

$$S_n(f) = N_0/2$$

$$\begin{aligned}
 &= \int_0^T \int_0^T E[n_w(t)n_w(\tau)]\phi_j(t)\phi_k(\tau)dtd\tau \\
 &= \int_0^T \int_0^T \frac{N_0}{2}\delta(t - \tau)\phi_j(t)\phi_k(\tau)dtd\tau
 \end{aligned}$$

- Using the property of a delta function $\int_{-\infty}^{\infty} g(t)\delta(t-a)dt = g(a)$ we have:

$$E[n_j n_k] = \frac{N_0}{2} \int_0^T \phi_j(\tau)\phi_k(\tau)d\tau = \begin{cases} \frac{N_0}{2}, & j = k \\ 0, & j \neq k \end{cases}$$

- Therefore, n_j and n_k ($j \neq k$) are uncorrelated Gaussian random variables
 - They are **independent** with **zero-mean** and **variance $N_0/2$**
- The joint pdf of $\vec{n} = (n_1, \dots, n_N)$

$$\begin{aligned} p(n_1, \dots, n_N) &= \prod_{k=1}^N p(n_k) = \prod_{k=1}^N \frac{1}{\sqrt{\pi N_0}} \exp(-n_k^2/N_0) \\ &= (\pi N_0)^{-N/2} \exp\left(-\sum_{k=1}^N n_k^2/N_0\right) \end{aligned}$$

Likelihood Function

- If m_k is transmitted, $\vec{r} = \vec{s}_k + \vec{n}$ with $r_j = s_{kj} + n_j$
- $E[r_j|m_k] = s_{kj} + E[n_j] = s_{kj}$

Transmitted signal values in each dimension represent the mean values for each received signal

- $Var[r_j|m_k] = Var[n_j] = N_0/2$
- Conditional pdf of the random variables $\vec{r} = (r_1, r_2, \dots, r_N)$

$$\begin{aligned} f(\vec{r}|m_k) &= \prod_{j=1}^N \frac{1}{\sqrt{\pi N_0}} \exp\left(-\frac{(r_j - s_{kj})^2}{N_0}\right) \\ &= (\pi N_0)^{-N/2} \exp\left(-\frac{\sum_{j=1}^N (r_j - s_{kj})^2}{N_0}\right) \end{aligned}$$

Log-Likelihood Function

- To simplify the computation, we take the **natural logarithm** of $f(\vec{r}|m_k)$, which is a monotonic function. Thus

$$\ln f(\vec{r}|m_k) = -\frac{N}{2} \ln(\pi N_0) - \frac{1}{N_0} \sum_{j=1}^N (r_j - s_{kj})^2$$

- Let

$$D^2(\vec{r}, \vec{s}_k) = \sum_{j=1}^N (r_j - s_{k,j})^2 = \|\vec{r} - \vec{s}_k\|^2$$

- $D(\vec{r}, \vec{s}_k)$ is the **Euclidean distance** between \vec{r} and \vec{s}_k in the N-dim signal space. It is also called **distance metrics**

Optimum Detector

- MAP rule:
$$\begin{aligned}\hat{m} &= \arg \max_{\{m_1, \dots, m_M\}} f(\vec{r}|m_k)P(m_k) \\ &= \arg \max_{\{m_1, \dots, m_M\}} \ln [f(\vec{r}|m_k)P(m_k)] \\ &= \arg \max_{\{m_1, \dots, m_M\}} \left\{ -\frac{1}{N_0} \|\vec{r} - \vec{s}_k\|^2 + \ln P_k \right\} \\ &= \arg \min_{\{m_1, \dots, m_M\}} \left\{ \|\vec{r} - \vec{s}_k\|^2 - N_0 \ln P_k \right\}\end{aligned}$$

- ML rule:
$$\hat{m} = \arg \min_{\{m_1, \dots, m_M\}} \|\vec{r} - \vec{s}_k\|^2$$

ML detector chooses $\hat{m} = m_k$ iff received vector \vec{r} is closer to \vec{s}_k in terms of Euclidean distance than to any other \vec{s}_i for $i \neq k$

Minimum distance detection

(will discuss more in decision region)

Optimal Receiver Structure

- From previous expression we can develop a receiver structure using the following derivation

$$\begin{aligned} - \sum_{j=1}^N (r_j - s_{kj})^2 + N_0 \ln P_k &= - \sum_{j=1}^N r_j^2 - \sum_{j=1}^N s_{kj}^2 + 2 \sum_{j=1}^N r_j s_{kj} + N_0 \ln P_k \\ &= -\|\vec{r}\|^2 - \|\vec{s}_k\|^2 + 2\vec{r} \cdot \vec{s}_k + N_0 \ln P_k \end{aligned}$$

in which

$$\|\vec{s}_k\|^2 = \int_0^T s_k^2(t) dt = E_k = \text{signal energy}$$

$$\vec{r} \cdot \vec{s}_k = \int_0^T s_k(t)r(t) dt = \text{correlation between the received signal vector and the transmitted signal vector}$$

$$\|\vec{r}\|^2 = \text{common to all } M \text{ decisions and hence can be ignored}$$

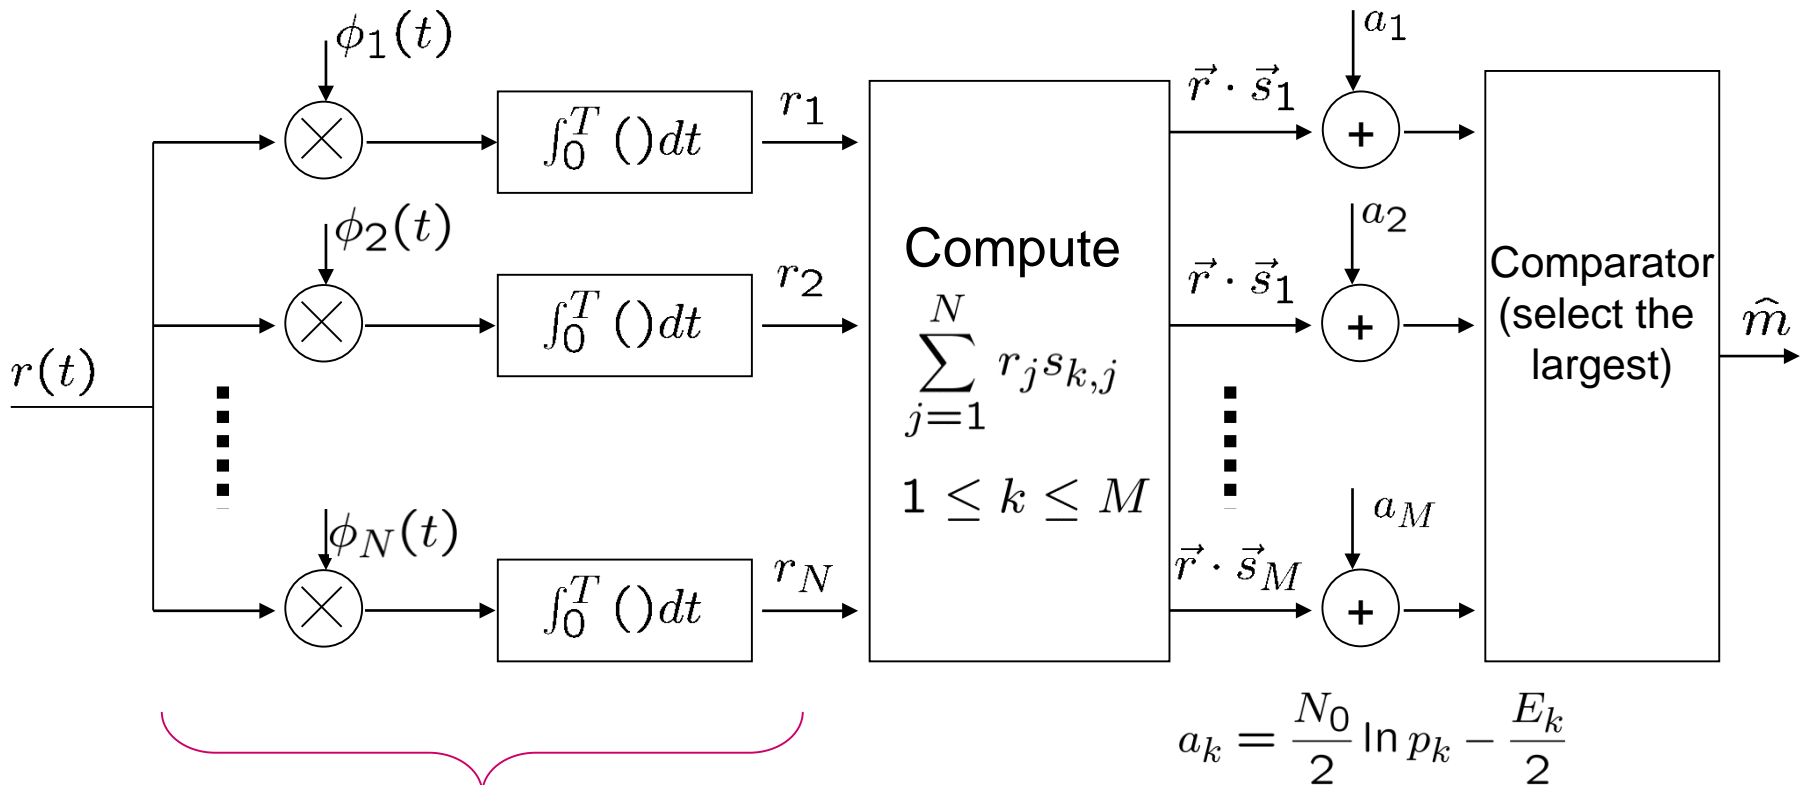

- The new decision function becomes

$$\hat{m} = \arg \max_{m_1, \dots, m_M} \left\{ \vec{r} \cdot \vec{s}_k - \frac{E_k}{2} + \frac{N_0}{2} \ln P_k \right\}$$

- Now we are ready draw the implementation diagram of MAP receiver (signal demodulator + detector)

MAP Receiver Structure

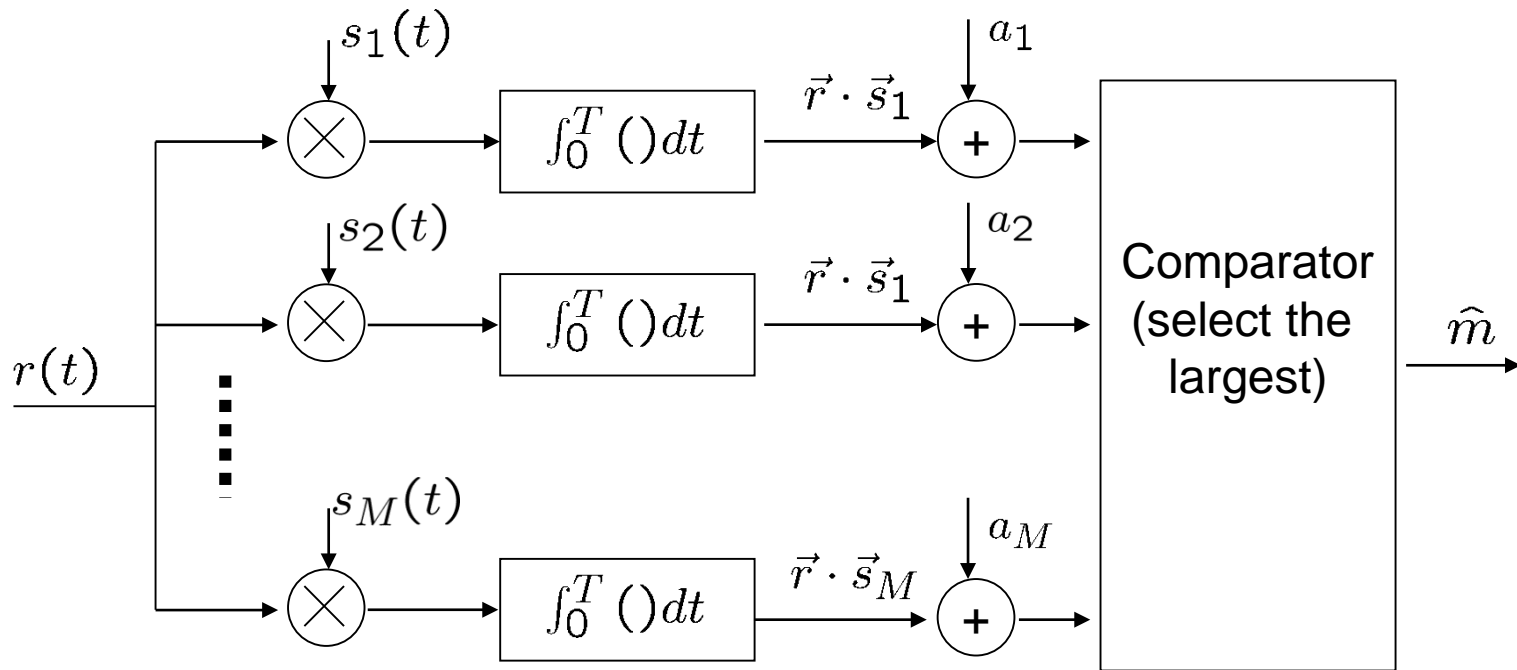

Method 1 (Signal Demodulator + Detector)

This part can also be implemented using matched filters

MAP Receiver Structure

Method 2 (Integrated demodulator and detector)

$$a_k = \frac{N_0}{2} \ln p_k - \frac{E_k}{2}$$

This part can also be implemented using matched filters

$$\hat{m} = \arg \max_{m_1, \dots, m_M} \left\{ \vec{r} \cdot \vec{s}_k - \frac{E_k}{2} + \frac{N_0}{2} \ln P_k \right\}$$

Method 1 vs. Method 2

- Both receivers perform identically
- Choice depends on circumstances
- For instance, if $N < M$ and $\{\phi_j(t)\}$ are easier to generate than $\{s_k(t)\}$, then the choice is obvious

Example: optimal receiver design

- Consider the signal set

Example (cont'd)

- Suppose we use the following basis functions

$$s_1(t) = 1\phi_1(t) + 1\cdot\phi_2(t)$$

$$s_2(t) = 1\phi_1(t) - 1\cdot\phi_2(t)$$

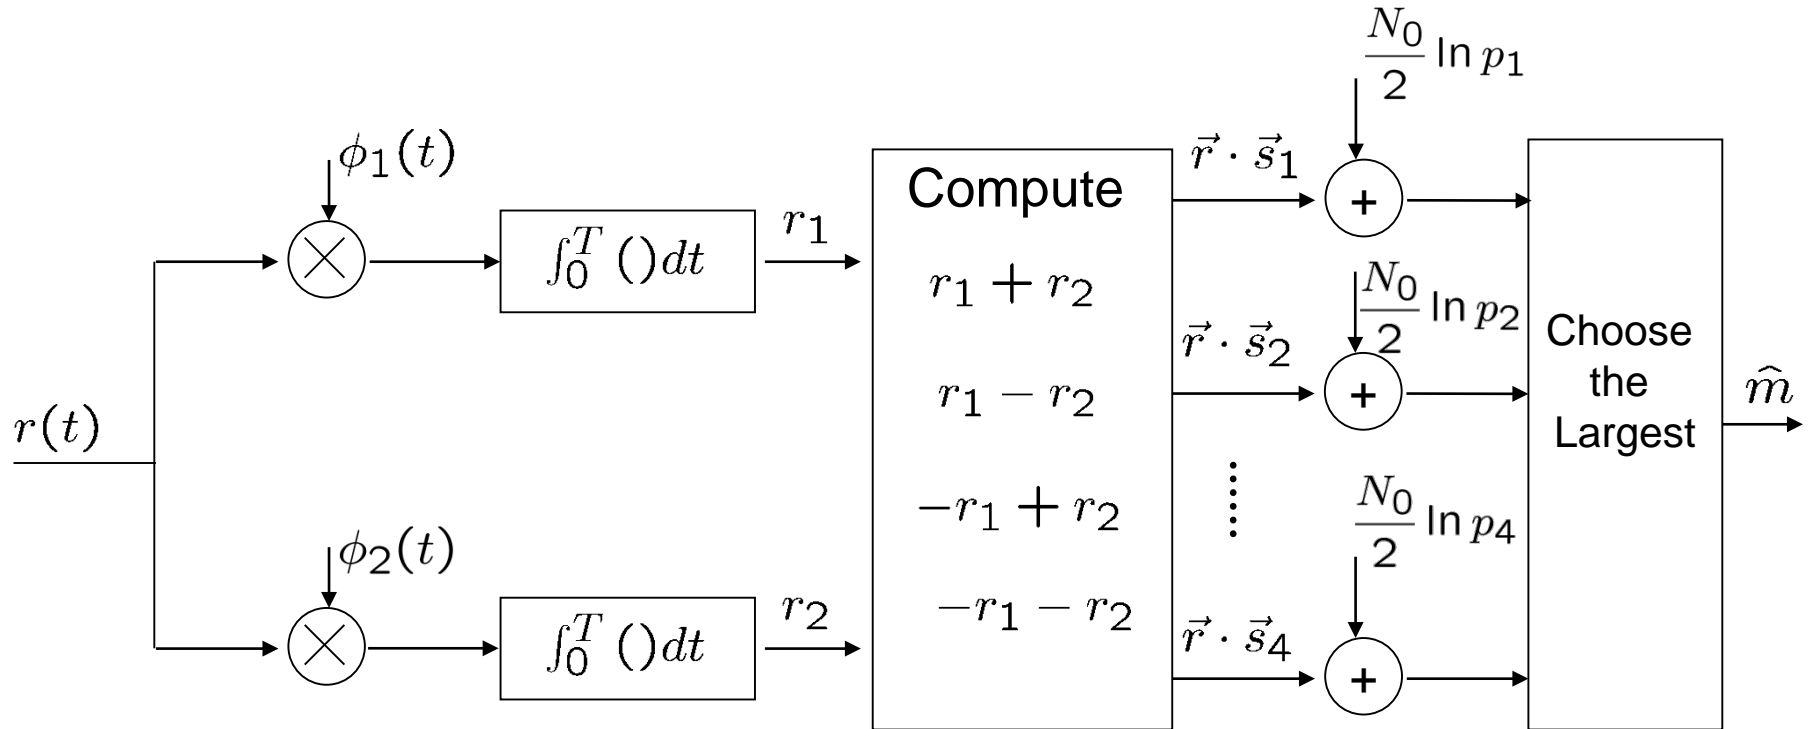

$$s_3(t) = -1\phi_1(t) + 1\cdot\phi_2(t)$$

$$s_4(t) = -1\phi_1(t) - 1\cdot\phi_2(t)$$

- Since the energy is the same for all four signals, we can drop the energy term from $a_k = \frac{N_0}{2} \ln p_k$

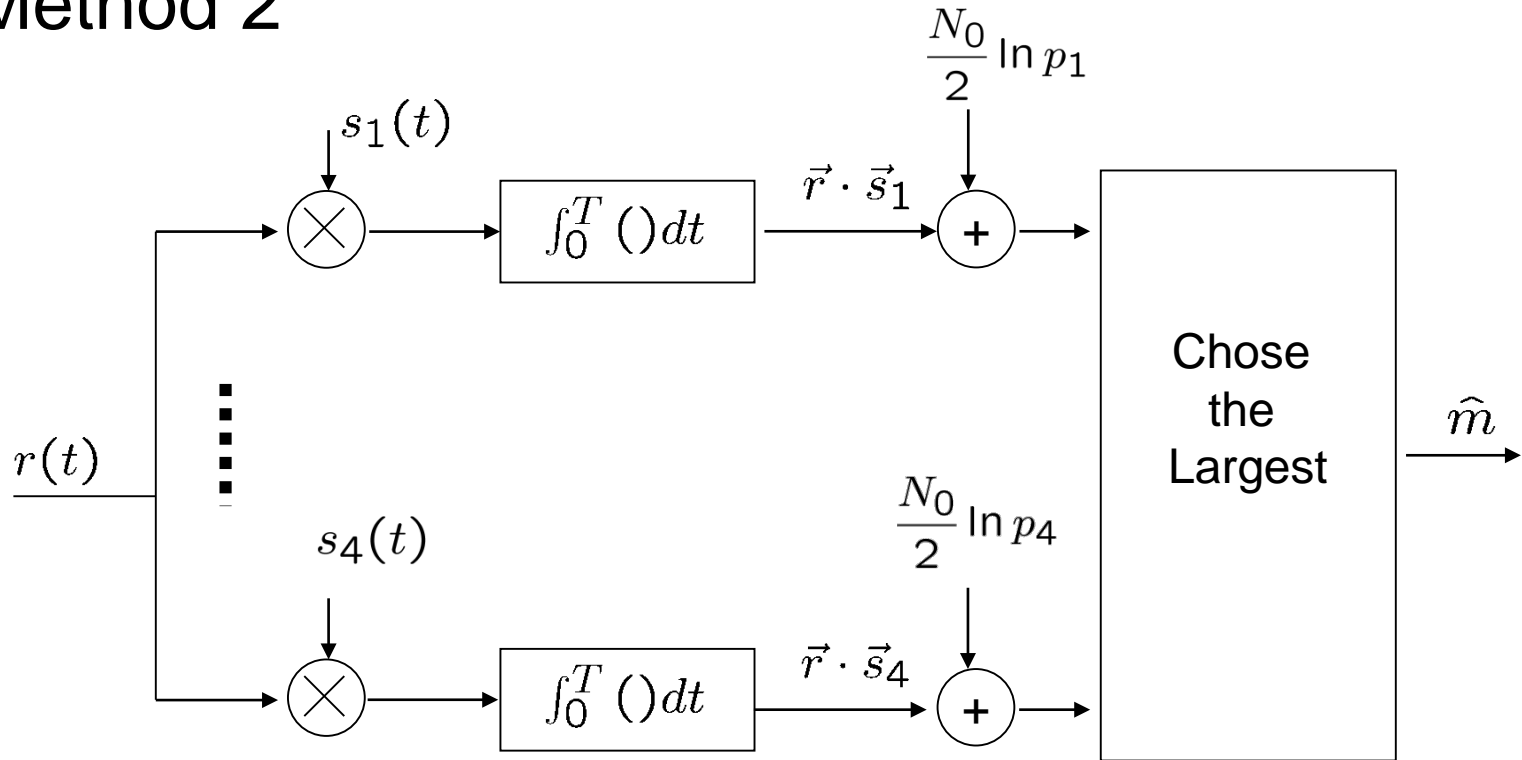

Example (cont'd)

- Method 1

Example (cont'd)

- Method 2

Exercise

In an additive white Gaussian noise channel with a noise power-spectral density of $N_0/2$, two equiprobable messages are transmitted by

$$s_1(t) = \begin{cases} \frac{At}{T} & 0 \leq t \leq T \\ 0 & \text{otherwise} \end{cases}$$

$$s_2(t) = \begin{cases} A - \frac{At}{T} & 0 \leq t \leq T \\ 0 & \text{otherwise} \end{cases}$$

- Determine the structure of the optimal receiver.

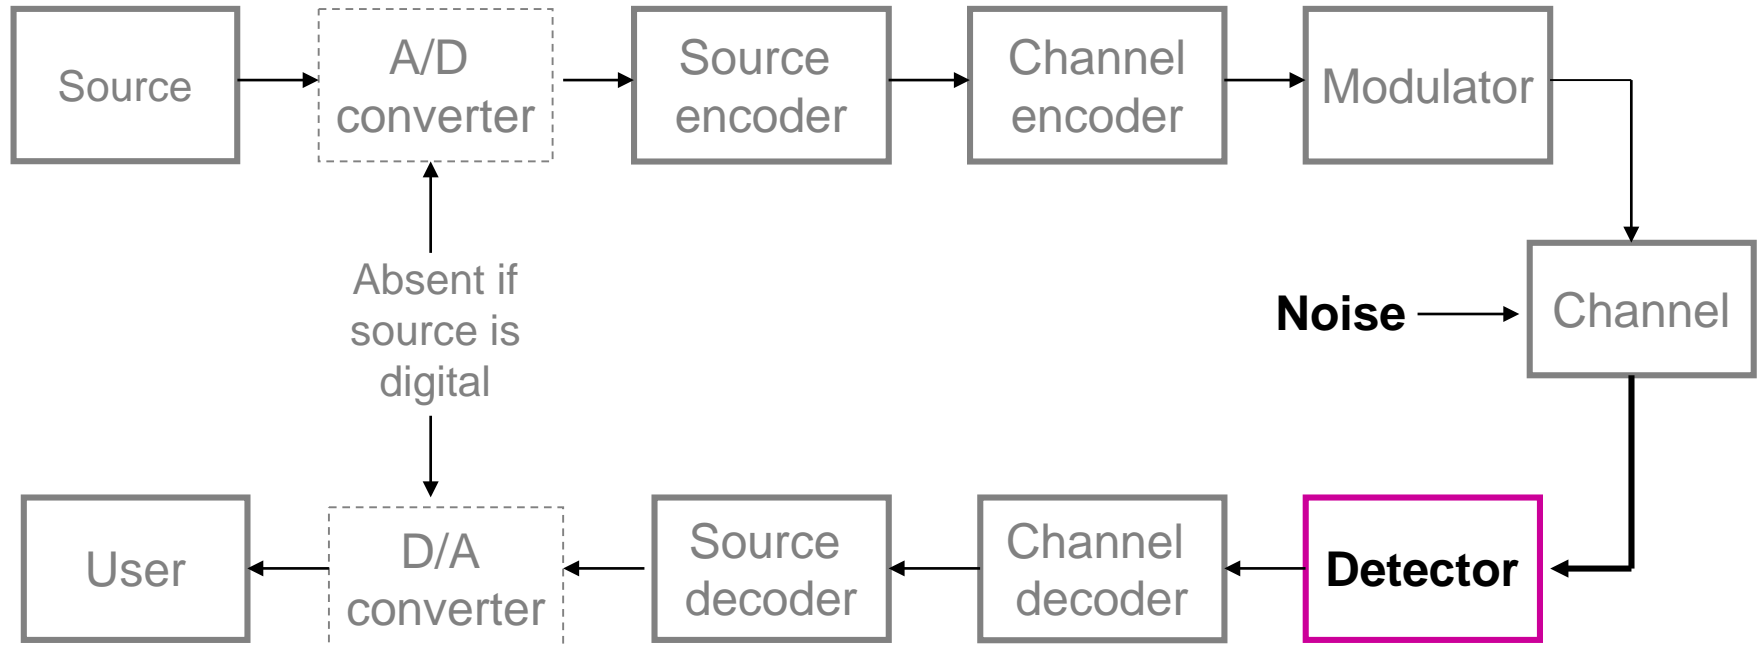

Notes on Optimal Receiver Design

- The receiver is general for any signal forms
- Simplifications are possible under certain scenarios

Topics to be Covered

- Detection theory
- Optimal receiver structure
- Matched filter
- Decision regions
- Error probability analysis

Graphical Interpretation of Decision Regions

- Signal space can be divided into M disjoint decision regions R_1, R_2, \dots, R_M .

If $\vec{r} \in R_k \implies$ decide m_k was transmitted

Select decision regions so that P_e is minimized

- Recall that the optimal receiver sets $\hat{m} = m_k$ iff

$$\|\vec{r} - \vec{s}_k\|^2 - N_0 \ln P_k \text{ is minimized}$$

- For simplicity, if one assumes $p_k = 1/M$, for all k , then the optimal receiver sets $\hat{m} = m_k$ iff

$$\|\vec{r} - \vec{s}_k\|^2 \text{ is minimized}$$

Decision Regions

- Geometrically, this means
 - Take projection of $r(t)$ in the signal space (i.e. \vec{r}). Then, decision is made in favor of signal that is the **closest** to \vec{r} in the sense of **minimum Euclidean distance**
 - And those observation vectors \vec{r} with $\|\vec{r} - \vec{s}_k\|^2 < \|\vec{r} - \vec{s}_i\|^2$ for all $i \neq k$ should be assigned to decision region R_k

Example: Binary Case

- Consider binary data transmission over AWGN channel with PSD $S_n(f) = N_0/2$ using

$$s_1(t) = -s_2(t) = \sqrt{E}\phi(t)$$

- Assume $P(m_1) \neq P(m_2)$
- Determine the optimal receiver (and optimal decision regions)

Solution

- Optimal decision making

Choose m_1

$$\|\vec{r} - \vec{s}_1\|^2 - N_0 \ln P(m_1) \underset{>}{<} \|\vec{r} - \vec{s}_2\|^2 - N_0 \ln P(m_2)$$

Choose m_2

- Let $d_1 = \|\vec{r} - \vec{s}_1\|$ and $d_2 = \|\vec{r} - \vec{s}_2\|$

- Equivalently,

Choose m_1

$$d_1^2 - d_2^2 \underset{>}{<} N_0 \ln \frac{P(m_1)}{P(m_2)}$$

Choose m_2

Constant c

$$R_1: d_1^2 - d_2^2 < c \quad \text{and} \quad R_2: d_1^2 - d_2^2 > c$$

Solution (cont'd)

- Now consider the example with \vec{r} on the decision boundary

$$\begin{cases} d = d_1 + d_2 \\ d_1^2 = \mu^2 \\ d_2^2 = (d - \mu)^2 \end{cases} \Rightarrow \begin{aligned} d_1^2 - d_2^2 &= 2d\mu - d^2 \equiv c \\ \mu &= \frac{c + d^2}{2d} = \frac{d}{2} + \frac{N_0}{2d} \ln \frac{P(m_1)}{P(m_2)} \end{aligned}$$

$$\mu \begin{cases} = d/2 & \text{if } P(m_1) = P(m_2) \\ > d/2 & \text{if } P(m_1) > P(m_2) \\ < d/2 & \text{if } P(m_1) < P(m_2) \end{cases}$$

Determining the Optimum Decision Regions

- In general, boundaries of decision regions are **perpendicular** bisectors of the lines joining the original transmitted signals
- Example: three equiprobable 2-dim signals

Example: Decision Region for QPSK

- Assume all signals are equally likely
- All 4 signals could be written as the linear combination of two basis functions
- Constellations of 4 signals

Exercise

Three equally probable messages m_1 , m_2 , and m_3 are to be transmitted over an AWGN channel with noise power-spectral density $N_0 / 2$. The messages are

$$s_1(t) = \begin{cases} 1 & 0 \leq t \leq T \\ 0 & \textit{otherwise} \end{cases}$$

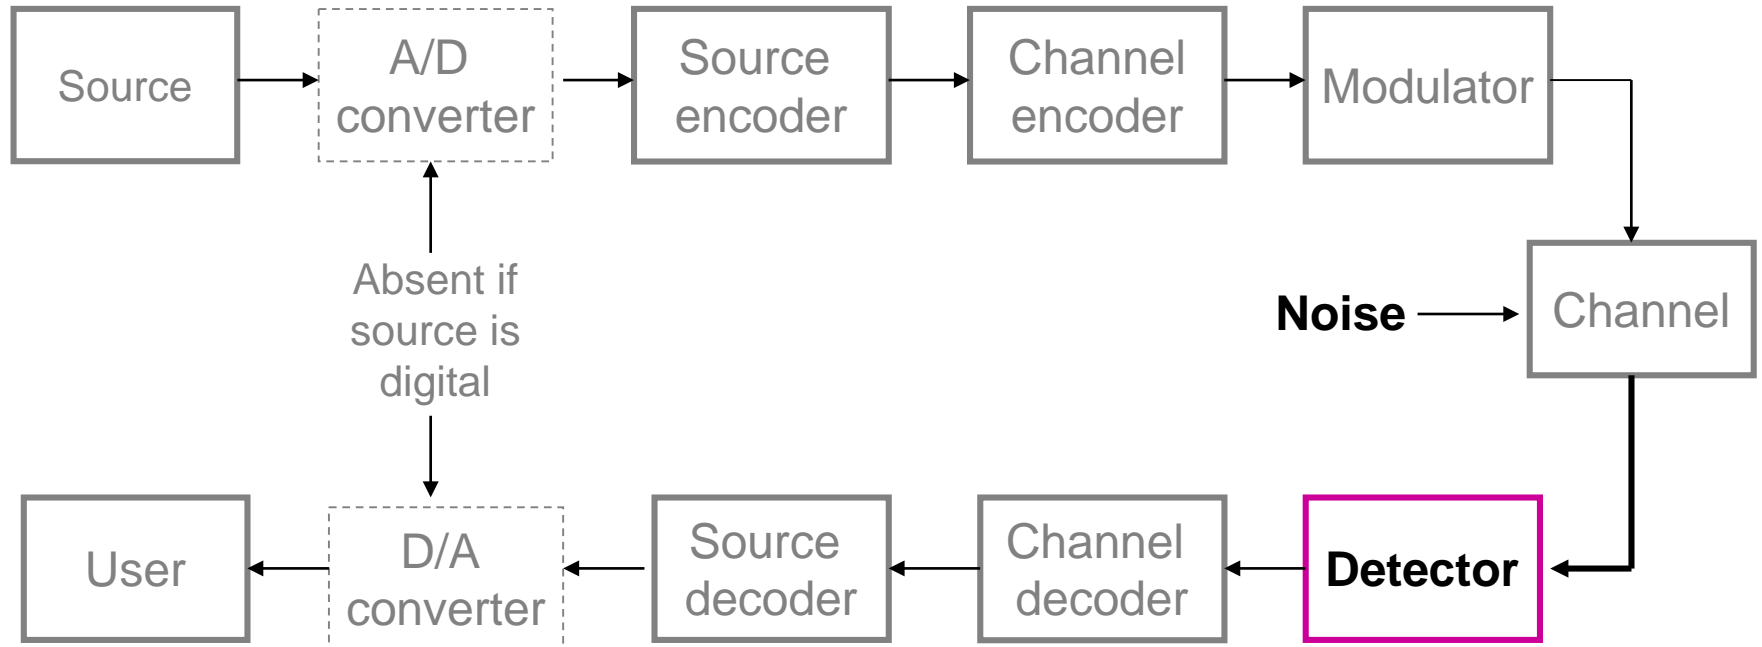

$$s_2(t) = -s_3(t) = \begin{cases} 1 & 0 \leq t \leq \frac{T}{2} \\ -1 & \frac{T}{2} \leq t \leq T \\ 0 & \textit{otherwise} \end{cases}$$

1. What is the dimensionality of the signal space ?
2. Find an appropriate basis for the signal space (Hint: You can find the basis without using the Gram-Schmidt procedure).
3. Draw the signal constellation for this problem.
4. Sketch the optimal decision regions R_1 , R_2 , and R_3 .

Notes on Decision Regions

- Boundaries are perpendicular to a line drawn between two signal points
- If signals are equiprobable, decision boundaries lie exactly halfway in between signal points
- If signal probabilities are unequal, the region of the less probable signal will shrink

Topics to be Covered

- Detection theory
- Optimal receiver structure
- Matched filter
- Decision regions
- **Error probability analysis**

Probability of Error using Decision Regions

- Suppose m_k is transmitted and \vec{r} is received
- Correct decision is made when $\vec{r} \in R_k$ with probability

$$P(C|m_k) = P(\vec{r} \in R_k | m_k \text{ is sent})$$

- Averaging over all possible transmitted symbols, we obtain the **average probability of making correct decision**

$$P(C) = \sum_{k=1}^M P(\vec{r} \in R_k | m_k \text{ is sent}) P(m_k)$$

- **Average probability of error**

$$P_e = 1 - P(C) = 1 - \sum_{k=1}^M P(\vec{r} \in R_k | m_k \text{ is sent}) P(m_k)$$

Example: P_e analysis

- Now consider our example with binary data transmission

- Given m_1 is transmitted, then

$$\begin{aligned} P(C|s_1) &= P(r \in R_1|s_1) \\ &= P(s_1 + n > d') \\ &= P(n > -\mu) \end{aligned}$$

- Since n is Gaussian with zero mean and variance $N_0/2$

$$\mu = \frac{d}{2} + \frac{N_0}{2d} \ln \frac{P(m_1)}{P(m_2)}$$

$$P(C|s_1) = 1 - Q\left(\frac{\mu}{\sqrt{N_0/2}}\right)$$

- Likewise

$$P(C|s_2) = P(s_2 + n < d') = P(n < d - u) = 1 - Q\left(\frac{d - \mu}{\sqrt{N_0/2}}\right)$$

- Thus,

$$\begin{aligned} P(C) &= P(m_1) \left\{ 1 - Q\left[\frac{\mu}{\sqrt{N_0/2}}\right] \right\} + P(m_2) \left\{ 1 - Q\left[\frac{d - \mu}{\sqrt{N_0/2}}\right] \right\} \\ &= 1 - P(m_1)Q\left[\frac{\mu}{\sqrt{N_0/2}}\right] - P(m_2)Q\left[\frac{d - \mu}{\sqrt{N_0/2}}\right] \end{aligned}$$

$$\Rightarrow P_e = P(m_1)Q\left[\frac{\mu}{\sqrt{N_0/2}}\right] + P(m_2)Q\left[\frac{d - \mu}{\sqrt{N_0/2}}\right]$$

where $d = 2\sqrt{E}$ and $\mu = \frac{N_0}{4\sqrt{E}} \log\left[\frac{P(m_1)}{P(m_2)}\right] + \sqrt{E}$

Example: P_e analysis (cont'd)

- Note that when $P(m_1) = P(m_2)$

$$\mu = \sqrt{E} = \frac{d}{2}$$

$$P_e = Q \left[\frac{d/2}{\sqrt{N_0/2}} \right] = Q \left[\sqrt{\frac{d^2}{2N_0}} \right] = Q \left[\sqrt{\frac{2E}{N_0}} \right]$$

Example: P_e analysis (cont'd)

- This example demonstrates an interesting fact:
 - When **optimal receiver** is used, P_e does not depend upon the specific waveform used
 - P_e depends only on their **geometrical representation in signal space**
 - In particular, P_e depends on signal waveforms only through their **energies (distance)**

$$P_e = Q \left[\frac{d/2}{\sqrt{N_0/2}} \right] = Q \left[\sqrt{\frac{d^2}{2N_0}} \right] = Q \left[\sqrt{\frac{2E}{N_0}} \right]$$

Exercise

Three equally probable messages m_1 , m_2 , and m_3 are to be transmitted over an AWGN channel with noise power-spectral density $N_0 / 2$. The messages are

$$s_1(t) = \begin{cases} 1 & 0 \leq t \leq T \\ 0 & \textit{otherwise} \end{cases}$$
$$s_2(t) = -s_3(t) = \begin{cases} 1 & 0 \leq t \leq \frac{T}{2} \\ -1 & \frac{T}{2} \leq t \leq T \\ 0 & \textit{otherwise} \end{cases}$$

1. What is the dimensionality of the signal space ?
2. Find an appropriate basis for the signal space (Hint: You can find the basis without using the Gram-Schmidt procedure).
3. Draw the signal constellation for this problem.
4. Sketch the optimal decision regions R_1 , R_2 , and R_3 .
5. Which of the three messages is more vulnerable to errors and why ? In other words, which of $p(\textit{Error} | m_i \textit{ transmitted})$, $i = 1, 2, 3$ is larger ?

General Expression for P_e

- Average probability of **symbol error**

$$P_e = 1 - P(C) = 1 - \sum_{k=1}^M P(\vec{r} \in R_k | m_k \text{ is sent}) P(m_k)$$

- Since $P(\vec{r} \in R_k | m_k \text{ is sent}) = \int_{R_k} f(\vec{r} | m_k) d\vec{r}$

N-dim integration

Likelihood function

- Thus we rewrite P_e in terms of likelihood functions, assuming that symbols are equally likely to be sent

$$P_e = 1 - \frac{1}{M} \sum_{k=1}^M \int_{R_k} f(\vec{r} | m_k) d\vec{r}$$

Union Bound

- Multi-dimension integrals are quite difficult to evaluate
- To overcome this difficulty, we resort to the use of **bounds**
- Now we develop a simple and yet useful upper bound for P_e , called **union bound**, as an approximation to the average probability of symbol error

Key Approximation

- Let A_{kj} denote the event that \vec{r} is closer to \vec{s}_j than to \vec{s}_k in the signal space when $m_k(\vec{s}_k)$ is sent
- Conditional probability of symbol error when m_k is sent

$$P(\text{error}|m_k) = P(\vec{r} \notin R_k|m_k) = P\left(\bigcup_{j \neq k} A_{kj}\right)$$

- But

$$P\left(\bigcup_{j \neq k} A_{kj}\right) \leq \sum_{\substack{j=1 \\ j \neq k}}^M P(A_{kj})$$

Key Approximation Example

$$A_{12} \cup A_{13} \cup A_{14}$$

A_{12}

A_{13}

A_{14}

Pair-wise Error Probability

- Define the **pair-wise** (or **component-wise**) **error probability** as

$$P(\vec{s}_k \rightarrow \vec{s}_j) = P(A_{kj})$$

- It is equivalent to the probability of deciding in favor of \vec{s}_j when \vec{s}_k was sent in a **simplified binary system** that involves the use of two equally likely messages \vec{s}_k and \vec{s}_j

- Then

$$P(\vec{s}_k \rightarrow \vec{s}_j) = P(n > d_{kj}/2) = Q\left(\sqrt{\frac{d_{kj}^2}{2N_0}}\right)$$

- $d_{kj} = \|\vec{s}_k - \vec{s}_j\|$ is the **Euclidean distance** between \vec{s}_k and \vec{s}_j

Union Bound

- Conditional error probability

$$P(\text{error}|m_k) \leq \sum_{\substack{j=1 \\ j \neq k}}^M P(\vec{s}_k \rightarrow \vec{s}_j) = \sum_{\substack{j=1 \\ j \neq k}}^M Q \left(\sqrt{\frac{d_{kj}^2}{2N_0}} \right)$$

- Finally, with M equally likely messages, the average probability of symbol error is upper bounded by

$$P_e = \frac{1}{M} \sum_{k=1}^M P(\text{error}|m_k) \\ \leq \frac{1}{M} \sum_{k=1}^M \sum_{\substack{j=1 \\ j \neq k}}^M Q \left(\sqrt{\frac{d_{kj}^2}{2N_0}} \right)$$

← The most general
formulation of union
bound

Union Bound (cont'd)

- Let d_{\min} denote the **minimum distance**, i.e.

$$d_{\min} = \min_{\substack{k,j \\ k \neq j}} d_{k,j}$$

- Since $Q(\cdot)$ is a monotone decreasing function

$$\sum_{\substack{j=1 \\ j \neq k}}^M Q\left(\sqrt{\frac{d_{kj}^2}{2N_0}}\right) \leq (M-1)Q\left(\sqrt{\frac{d_{\min}^2}{2N_0}}\right)$$

- Consequently, we may simplify the union bound as

$$P_e \leq (M-1)Q\left(\sqrt{\frac{d_{\min}^2}{2N_0}}\right) \quad \leftarrow \text{Simplified form of union bound}$$

Question

What is the design criterion of a good signal set?
